1 Introduction

The NGA-East project developed ground-motion models (GMMs) for a reference hard-rock site condition with V_{S30}=3000 m/s and $\kappa_0 = 0.006sec$ (Goulet et al., 2018). For application to site conditions other than hard rock, site factors are needed to adjust the NGA-East hard-rock GMMs to soft-rock or soil site conditions. Site factors developed to be applicable to the NGA-East hard-rock GMMs were subsequently developed by an expert panel (Stewart et al., 2020). These site factors have been used by the U.S. Geological survey in the computation of the recent U.S. national uniform hazard maps for CENA sites.

*abrahamson@berkeley.edu
†kofi.addo@bchydro.com
‡pacificengineering@juno.com

Using the Stewart et al. (2020) site factors to estimate response spectra for soft-rock conditions (V_{S30}=760 m/s) leads to a large increase in the short-period content compared to the NGA-W2 GMMs for the same site condition. For example, Figure 1 shows the pseudo spectral acceleration (PSA) for a magnitude 6 earthquake at a distance of 20 km using the central NGA-East GMM for hard-rock conditions, the central NGA-East GMM with the median Stewart et al. (2020) site factors for V_{S30}=760 m/s, and the average NGA-W2 for V_{S30}=760 m/s. The short-period ($T < 0.1$) PSA values for V_{S30} = 760 m/s for a CENA site are 3-5 times larger than for a Western North America (WNA) site with the same V_{S30}; however, as will be shown later, this large increase is not seen in the NGA-East data for soft-rock conditions.

The key issue is that the site terms used by the NGA-East GMM developers to adjust the NGA-East ground-motion data to hard-rock site conditions were developed independently of the site terms used to adjust the NGA-East hard-rock GMM back to soft-rock conditions. Stewart et al. (2020) noted that the SR/HR site factors should be developed as part of the GMM rather than being developed in an independent study. If the site factors are developed independently of the GMMs, there can be inconsistencies that can lead to a bias in the computed ground motions.

The objective of this study is to check the consistency between the soft-rock ground-motion data in the NGA-East database and the NGA-East hard-rock GMMs with the Stewart et al. (2020) SR/HR site factors. In other words, if we close the loop, do the Stewart et al. (2020) soft-rock / hard-rock (SR/HR) site factors reflect the inverse of the HR/SR site factors used in the development of the NGA-East GMMs? In developing site factors to apply to the NGA-East hard-rock GMMs, the question is not what is the correct site factors between a hard-rock site and a soft-rock site in eastern North America but what site factors should be applied to the NGA-East hard-rock GMMs that will be consistent with the methods used by the developers of the NGA-East GMMs to adjust the observed ground motions on soil and soft-rock conditions to hard-rock conditions.

2 HR/SR factors used by NGA-East GMM Developers

In the NGA-East project, the reference hard-rock site condition (V_{S30}=3000 m/s and κ_0 =0.006 sec) was fixed, but the available empirical ground-motion data set compiled by the NGA-East project (Goulet et al., 2014) was sparse in terms of ground-motion data from hard-rock sites. For example, for rupture distances less than 150 km, 20% of the sites have $1500 \geq V_{S30} \leq 2000$ m/s and there are no sites with $V_{S30} > 2000$ m/s. The distributions of V_{S30} for sites at distances less than 100 km and less than 150 km are shown in Figure 2. Therefore, the developers of the NGA-East seed GMMs had to adjust either the observed ground motions or their GMMs for soft-rock conditions to the specified reference hard-rock site condition.

The approach for converting the ground motions to the reference hard-rock condition was not specified in the NGA-East Project. The idea was that this conversion should be part of the epistemic uncertainty in the final GMM. Therefore, each developer of the seed GMMs selected their own method to adjust the as-recorded ground motions or their empirical model for soft-rock conditions to the reference hard-rock site condition (Goulet et al., 2015).

Because the NGA-East GMM developers used different approaches to correct the recorded ground motions to hard-rock conditions, and the seed models were later categorized into the 17 representative models, it is difficult to determine the HR/SR factors that were used in the individual NGA-East GMM. Therefore, in this paper, we simply evaluate how well the central NGA-East hard-rock GMM, combined with a set of SR/HR site factors, fits the observed CENA soft-rock ground-motion data.

3 Stewart et al Site Factors

The Stewart et al. (2020) site factors included a linear site term as well as a nonlinear site term. This evaluation is focused on the linear site term. In the Stewart et al. (2020) model, the linear

site term has the form:

$$f_{lin} = F_V(V_{S30}, T) + F_{760}(V_{S30}, T) \tag{1}$$

in which $F_{760}(T)$ is the linear site term to adjust the PSA values from the NGA-East hard-rock site condition (V_S=3000 m/s, κ_0=0.006 sec) to V_{S30}=760 m/s, and $f_V(V_{S30}, T)$ is the linear site term to adjust the PSA values from V_{S30}=760 m/s to the desired V_{S30} value.

Stewart et al. (2020) used analytical modeling of 1-D site response to estimate the F_{760} term. Multiple methods with alternative V_S profiles were considered. Two sets of site factors were developed for two alternative V_S profiles: F_{760_IMP} for V_S profiles with a strong impedance contrast leading to site resonance near T=0.1 sec; and F_{760_gr} for V_S profiles with a gradient rather than a strong impedance contrast.

The two sets of recommended F_{760} factors are shown in Figure 3. These give the median site terms with associated epistemic uncertainties judged to be appropriate by the expert panel. As noted in Stewart et al. (2020), a limitation for the F_{760} term is that it is only based on analytical modeling and does not include checks or constraints with observed ground motions.

4 Data Set

The ground-motion data sets in the CENA have grown significantly since the NGA-East database was compiled; however, the objective of this study is to simply check if the NGA-East soft-rock data, the hard-rock GMM, and the Stewart et al. (2020) SR/HR site factors are internally consistent. Therefore, we have not expanded the data set to include recent recordings that were not part of the initial NGA-east database.

The full NGA-East data set has 9382 recordings, but a much smaller subset is applicable for the evaluation of the compatibility of the NGA-East hard-rock GMMs and the Stewart et al. (2020) short-period site factors for soft-rock site conditions. The final NGA-East GMMs are non-parameteric tables of ground-motion values and are defined for $M \geq 4$, so only earthquakes with

magnitudes greater than or equal to 4.0 are used to avoid extrapolating the NGA-East GMMs to smaller magnitudes. To limit the distance effects on the site factors for PSA at short periods, the rupture distances are initially limited to 200 km. An evaluation of the distance effects on the site factors is given in the next section. The magnitude-distance distribution of the data with rupture distances less than 200 km and with V_{S30} between 500 and 1000 m/s are shown in Figure 4.

Based on the filtering applied to the recordings, the useable period range of the data is listed in the NGA-East data file. At very short periods (e.g. at periods much shorter than the peak in the PSA), the PSA values are not sensitive to the low-pass filters used in the data processing. This allows the useable period range to be extended to periods less than the filter corner period. For spectral periods less than 0.03 sec, the PSA values are considered reliable if the corner period of the low-pass filter is less than 0.025 sec.

5 Empirical SR/HR Site Factors from NGA-East

Empirical estimates of the SR/HR factors are computed using the residuals computed relative to the NGA-East central GMM for the reference hard-rock site condition. The residuals are plotted as functions of distance and V_{S30} in Figure 5. These figures show a distance trend in the short-period residuals with increased residuals at distances greater than 150 km. This distance dependence may reflect differences in the distance attenuation (e.g. effects of post-critical reflections from the Moho) or Q effects. To avoid complex distance attenuation and Q effects affecting the short-period site terms, distance limits of 70, 100, and 150 km are used.

To evaluate the site factors for the soft-rock (V_{S30} = 760 m/s) site condition, we selected two subsets of data based on the V_{S30} value: $650 < V_{S30} < 900$ m/s and $500 < V_{S30} < 1000$ m/s. The number of recordings in each subset (distance range of V_{S30} range) is listed in Table 1. For the shorter distance limits (70 and 100 km), the available empirical data is very sparse, with between 12 and 52 recordings, depending on the distance and V_{S30} range. With this criteria, the number of useable recordings is shown as a function of period in Figure 6.

For the narrow V_{S30} range (650 - 850 m/s), the individual residuals and the mean residuals at each spectral period are shown in Figure 7 for distance limits of 100 and 150 km. The empirical SR/HR factors show a peak in the amplification in the 0.1 to 0.15 sec range, consistent with the Stewart et al. (2020) F_{760_IMP} site factors. The SR/HR site factors at periods greater than 0.15 sec are also consistent with the Stewart et al. (2020) F_{760_IMP} site factors. At very short periods ($T < 0.075$ sec), there is a large discrepancy between the empirical SR/HR factors and the F_{760_IMP} factors with the empirical SR/HR factors being smaller by up to a factor of 2.

Using the wider V_{S30} range increases the number of recordings, but may introduce a bias due to the V_{S30} scaling. Therefore, for the subset that includes lower V_{S30} values ($500 < V_{S30} < 1000m/s$), the residuals computed with respect to the NGA-East hard-rock GMM are modified to include the effects of F_V scaling given in the Stewart et al. (2020) model.

$$resid_i(T) = Obs_i(T) - Med_{HR}(M_i, R_i, T) - f_V(V_{S30}, T) \tag{2}$$

Figure 8 shows the mean residuals for $R_{RUP} < 70km$ and for $R_{RUP} < 100km$. Using the larger datasets with the wider range of V_{S30}, the resonance at T=0.1 to T=0.15 sec is not seen, but the large overprediction of the short-period ground motion is still observed.

6 Analytical SR/HR Site Factors

Following a similar approach as used by Stewart et al. (2020), we used analytical modeling of the site response to estimate the SR/HR factor. The analytical site factors are estimated by the ratio of the surface motions from the site response for two profiles, the reference hard-rock site and the target soft-rock profile. The V_S profile for used for the soft-rock site is gradient profile shown in Figure 9.

The SR/HR ratio was computed for κ_0 values of 0.02, 0.03, and 0.04 sec for the soft-rock site. Figure 10 compares the analytical results to the empirical SR/HR terms based on the mean residuals using subsets of the data for four different V_{S30} and R_{RUP} ranges. For this V_S profile, a

κ_0 of 0.03 sec leads to site factors that are generally consistent with the empirical SR/HR factors at short periods from the NGA-East data. At long periods, the analytical site factors for gradient profile lead to less amplification than the empirical factors, indicating that there is a difference in the deeper V_S profile for the soft-rock site that is not captured in the gradient profile shown in Figure 9.

Figure 11 compares the two Stewart et al. (2020) models for F_{760} with the mean residuals for the different subsets of NGA-East data and with the analytical results of the PEA model with κ_0=0.03 sec. The Stewart et al. (2020) F_{760_IMP} model is consistent with the mean residuals from the narrow V_{S30} range (650-850 m/s) for periods between 0.1 and 0.5 sec, and it captures the site resonance at T=0.12 sec; however, at periods less than 0.1 sec, the F_{760_IMP} model significantly overestimates the mean residuals. The Stewart et al. (2020) F_{760_gr} model is consistent with the mean residuals from the wider V_{S30} range (500-1000 m/s) that do not show as strong of a resonance at T=0.12 sec, but leads to much larger amplification at periods between 0.3 and 0.6 sec. The F_{760_gr} model also significantly overestimates the mean residuals at very short periods.

7 Model for SR/HR site factors for NGA-East

Based on the comparisons with the empirical SR/HR site factors, new SR/HR site factors are proposed as shown in Figure 12. Similar to the Stewart et al. (2020) approach, two SR/HR factors are proposed: Model 1 based on the strong impedance contrast that leads to the peak in the SR/HR factors near T=0.1 sec and Model 2 based on the wider range of V_{S30} values that does not show the resonance at T=0.1 sec.

For Model 1, the SR/HR factors are based the analytical results periods of 0.02 to 0.2 sec. At periods less than 0.02 sec, the model is lower than the analytical factors so that when combined with the NGA-East hard-rock GMM, the shape of the spectrum at periods less than 0.02 sec is appropriate (i.e., the spectrum does not increase). At periods from 0.2 to 1 sec, Model 1 follows the Stewart et al. (2020) SR/HR factors.

For Model 2, the SR/HR factors at periods less than 0.08 sec capture the lower part of the empirical SR/HR range. For periods from 0.08 to 0.2 sec, the model is based on the empirical site factors for V_{S30} between 500 and 1000 m/s. At periods from 0.2 to 1.0 sec, Model 2 is based on the empirical SR/HR factors and the F_{760_gr} model for periods greater than 2 sec.

The SR/HR site factors for the two models are listed in Table 2. Using these site factors, the response spectra for the M=6, R_{RUP}-20 km scenario are shown in Figure 13 along with the NGA-East GMM for hard-rock sites and the NGA-W2 for soft-rock sites. Compared with Figure 1, soft-rock sites in the eastern U.S still show a large increase in the short-period ground motion compared to sites in the western U.S., but the difference is reduced for periods less than 0.1 sec.

8 Conclusions

At short periods ($T < 0.1$ sec), there is a large discrepancy between the Stewart et al. (2020) F_{760} site terms and the empirical F_{760} site terms. Most buildings are not sensitive to the PSA at periods less than 0.1 sec, but for structures, systems, and components that are sensitive to these short periods, such as safety-related equipment in nuclear power plants and concrete dams, the SR/HR site factors given by Stewart et al. (2020) are not applicable to the NGA-East GMMs. As an alternative, we recommend using the SR/HR site factors listed in Table 2 to adjust the NGA-East hard-rock GMMs.

The discrepancy in the short-period site terms is likely a result of the site terms for the NGA-East hard-rock GMMs being developed independent of the development of the hard-rock site GMM which also used term factors to adjust the observed ground-motion data to hard-rock conditions. One possible explanation for this mismatch of the NGA-East GMM and the site factors for short periods may be that the NGA-East GMMs overestimated the effect of kappa on the short-period ground motions for the hard-rock site condition with $\kappa = 0.006sec$, as suggested by the empirical analysis of hard-rock site residuals by Ktenidou and Abrahamson (2016). That is, the Stewart et al. (2020) F_{760} site terms may be appropriate for correcting hard-rock ground motions to soft-

rock conditions, but these site factors are not consistent with the NGA-East hard-rock ground motions due to the large kappa effects included in NGA-East GMMs.

If analytical modeling of the site response is used, the consistency between the site response and the factors used to adjust the soft-rock ground motions to hard-rock conditions should be carefully considered. Simply using the NGA-East hard-rock ground motions as inputs to a site-specific analysis with a thin soil profile will lead to the same overprediction of the short-period ground motions that was seen for the analytical modeling by Stewart et al. (2020).

This study addressed the consistency between the NGA-East hard-rock GMM and the Stewart et al. (2020) F_{760} site terms using the NGA-East data. The empirical evaluation of the SR/HR site factors should be extended to include the more recent ground-motion data in Eastern North America to develop improved empirical constraints on the site factors. In addition, future updates of the hard-rock ground-motion models for Eastern North America should re-evaluate the kappa scaling with an emphasis on separating how much of the lower kappa values for hard-rock sites represents damping and how much represents site amplification in the high-frequency range.

DB Wilson Station Phase I

Special Waste Landfill Postclosure Plan

January 20, 2021

Introduction

Big Rivers Electric Corporation (BREC) operated a special waste landfill in Ohio County, Kentucky. The special waste landfill was used for the disposal of fly ash, bottom ash and stabilized scrubber wastes. These wastes met the definition of "coal combustion by-products" given in 401 KAR 45:010 and "special waste" given in KRS 224.50-760(1) (a). These wastes are generated by the 440-megawatt D.B. Wilson Power Plant. The landfill is separated into two phases, Phase 1 and Phase 2. Both phases of the special waste landfill are situated on a reclaimed surface mine. It is the intention of BREC to close Phase 1 of the D.B. Wilson Station Special Waste Landfill. Following the closure of the Phase 1 Landfill, a Postclosure Plan lasting a five (5) year period of maintenance and monitoring is being submitted.

The purpose of this Postclosure Plan is to meet the requirements given in 401 KAR 45:110. These regulations set certain criteria for the postclosure care of a special waste landfill. This Postclosure Plan addresses these care criteria performed by BREC to ensure no adverse effects occur to human health and the environment. The scope of the plan will include:

- Groundwater Monitoring Scheduling
- Maintenance Scheduling
- Projected postclosure cost estimate
- Postclosure plan conformance.

1. Written Postclosure Plan

As per 401 KAR 45:110:

(i) A post closure plan shall be submitted by the owner or operator of the special waste landfill that includes a monitoring and maintenance schedule for the landfill and a postclosure cost estimate in accordance with Section 3 of 401 KAR 45:080.

(ii) Upon completion of the implementation of an approved closure plan, a special waste landfill shall be maintained under its postclosure plan for a minimum of five (5) years in a manner that complies with 401 KAR 30:031.

(iii) At the conclusion of the five (5) year postclosure monitoring period, the owner or operator of the special waste landfill shall submit a certification that closure and postclosure of the site is complete in accordance with the approved closure and postclosure plans, and that the site is in conformance with the terms of this chapter and 401 KAR 30:031. The cabinet shall review the certification, conduct a site visit and review the permit records to determine if the site is closed in accordance with this chapter, 401 KAR 30:031, and KRS Chapter 224. If the certification of closure is accurate and there is no outstanding environmental violations at the site, the cabinet shall accept the certification of closure and, within

180 days of accepting the certification, release any remaining financial assurance executed under 401 KAR 45:080.

(iv) Any necessary environmental remediation steps or corrective action for groundwater contamination required under 401 KAR 45:160 shall be performed before the special waste landfill postclosure is certified as complete and financial assurance is released.

1.1 Final Cover System

Following the closure of the DB Wilson Phase I Landfill, visual inspections of the site and the Closure Turf cap will be completed on an annual basis for the duration of the postclosure period, five (5) years. Maintenance or any other corrective measures that are needed to prevent the deterioration of the closure system will be identified during the inspections.

The cap system will be maintained for a minimum of 5 years following final closure of the DB Wilson Phase I Landfill. The effectiveness of the cap system will be maintained by infilling sand to uphold the integrity of the turf cap, as well as any other necessary repairs to the cap.

1.2 Leachate Collection and Removal System

Big Rivers will maintain the integrity and effectiveness of the leachate collection and treatment system. Maintenance and monitoring of the leachate collection system during the postclosure period will include inspecting of the open channel flumes that will be installed in place of the current downspout pipes. Also due to the potential migration of the leachate, groundwater monitoring will be a part of the postclosure plan.

1.3 Groundwater Monitoring System

Big Rivers will handle the groundwater monitoring and analysis for the postclosure period. Groundwater monitoring locations will be inspected annually, and repairs will be made as needed.

1.4 Postclosure Cost Estimation

Based on Groundwater Monitoring, Leachate Treatment, and Operation and Maintenance cost projections an estimated Post Closure Care Total cost was calculated to be $117,270 annually, with a cost per year per acre of $1,339.

The Postclosure Cost Estimate can be found in **Attachment 4.**

1.5 Certification of Postclosure Plan

There is a written certification provided by a qualified professional engineer that states that the post closure plan has met the requirements of 401 KAR 45:110.

1.6 Notification of Completion of Post Closure Care Period

No later than 180 days following the completion of the postclosure period of five years, the owner or operator must prepare a notification verifying that the postclosure care has been completed. The notification must include a certification by a qualified professional engineer verifying that postclosure care has been completed in accordance with the postclosure plan and requirements of 401 KAR 30:031.

Professional Engineer Certification [Per 40 CFR §257.91 and §257.93]

I hereby certify that myself or an agent under my review has prepared this Groundwater Monitoring System and Statistical Method Assessment and being familiar with the provisions of the final rule to regulate the disposal of coal combustion residuals (CCR) as solid waste under subtitle D of the Resource Conservation and Recovery Act (RCRA), attest that:

- The Groundwater Monitoring System meets the requirements of § 257.91 as specified below:

  (f) The owner or operator must obtain a certification from a qualified professional engineer stating that the groundwater monitoring system has been designed and constructed to meet the requirements of this section. If the groundwater monitoring system includes the minimum number of monitoring wells specified in paragraph (c)(1) of this section, the certification must document the basis supporting this determination.

- The Statistical Method meets the requirements of § 257.93 as specified below:

  (f)(6) The owner or operator of the CCR unit must obtain a certification from a qualified professional engineer stating that the selected statistical method is appropriate for evaluating the groundwater monitoring data for the CCR management area. The certification must include a narrative description of the statistical method selected to evaluate the groundwater monitoring data.

Certification Statement 40 CFR § 257.93(f)(6) – Statistical Method for the Evaluation of Groundwater Monitoring Data for the CCR Management Area

CCR Landfill Information

Name: D.B. Wilson CCR Landfill
Operator: D.B. Wilson Generating Station
Address: 5663 State Route 85 West, Centertown, KY 42328

I, Michael Brian Cole, PE, being a Registered Professional Engineer in good standing in the Commonwealth of Kentucky, do hereby certify, to the best of my knowledge, information, and belief that the information contained in this certification is prepared in accordance with the accepted practice of engineering. I certify, for the above-referenced CCR Unit, that the statistical method selected for the groundwater monitoring system as included in the 2016-2017 Annual Groundwater Monitoring and Corrective Action Report for the Wilson Phase II Landfill dated 1/29/2017 is appropriate for evaluating the groundwater monitoring data for the CCR Unit. The statistical method selected to evaluate the groundwater monitoring data for the CCR Unit is identified in the 2016-2017 Annual Groundwater Monitoring and Corrective Action Report, Section 3.4, Attachment C dated 1/29/2017 for the Wilson Phase II Landfill.

KEY ASSUMPTIONS

The following key assumptions and limitations are associated with the project design, implementation and performance:

1	The cost estimates were prepared using 2020 dollars and do not include any escalation.
2	No costs to improve the existing sediment basins or to regrade the perimeter ditch have been included.
3	The unit rate costs are based on AECOM experience, RS Means, and recent quotes from Watershed Geo on a hypothetical project of this size.
4	No costs to convey seepage to existing treatment system have been included.
5	It is assumed that the existing perimeter ditch profile provides adequate drainage, and no significant improvements are required.
6	Abandonment of existing structures/piping includes the demolition of existing pipes and inlets/outlet structures, and converting the resulting trench into a rip rap flume. There may be some grouting of outlet pipes that extend beyond the limits of waste.
7	Cap cross section for the CCR landfill will consist of (from bottom to top): cover soil / geomembrane / closure turf / sand infill.
8	Statements of Probable Construction Cost prepared by AECOM represent AECOM's judgment as a design professional familiar with the construction industry. It is recognized, however, that neither AECOM nor the Owner has control over the cost of labor, materials or equipment nor over the contractor's methods of determining the bid price or other competitive bidding, market, or negotiating conditions. Accordingly, AECOM cannot and does not warrant or represent that proposals, bids or actual construction costs will not vary from any statement of Probable Construction Cost or other estimates or evaluations prepared by AECOM.

KEY ASSUMPTIONS

The following key assumptions and limitations are associated with the project design, implementation and performance:

1	The cost estimates were prepared using 2020 dollars and do not include any escalation.
2	No costs to improve the existing sediment basins or to regrade the perimeter ditch have been included.
3	The unit rate costs are based on AECOM experience, RS Means, and recent quotes from Watershed Geo on a hypothetical project of this size.
4	No costs to convey seepage to existing treatment system have been included.
5	It is assumed that the existing perimeter ditch profile provides adequate drainage, and no significant improvements are required.
6	Abandonment of existing structures/piping includes the demolition of existing pipes and inlets/outlet structures, and converting the resulting trench into a rip rap flume. There may be some grouting of outlet pipes that extend beyond the limits of waste.
7	Cap cross section for the CCR landfill will consist of (from bottom to top): cover soil / geomembrane / closure turf / sand infill.
8	Statements of Probable Construction Cost prepared by AECOM represent AECOM's judgment as a design professional familiar with the construction industry. It is recognized, however, that neither AECOM nor the Owner has control over the cost of labor, materials or equipment nor over the contractor's methods of determining the bid price or other competitive bidding, market, or negotiating conditions. Accordingly, AECOM cannot and does not warrant or represent that proposals, bids or actual construction costs will not vary from any statement of Probable Construction Cost or other estimates or evaluations prepared by AECOM.

Interface Direct Shear Testing Results

Subject: Interface Shear Test Results Submittal
ClosureTurf® Final Cover System
Wilson Station Phase 1 Landfill Closure Cap, Centertown, KY

Dear Mr. Sneed,

As required by the Construction Quality Assurance (CQA) Plan for the above referenced project, Watershed Geosynthetics LLC has enclosed third party (TRI Environmental, Austin, TX) interface shear test results documenting the interface shear performance between the geomembrane component of the ClosureTurf® Final Cover System and the underlying subgrade soil.

Should you require addition information, please do not hesitate to contact me at (502) 209-0325. Thank you for your business.

Respectfully,

Steven M. Mayes, P.E.

AECOM ASSUMPTION SHEET	PROJECT: **DB WILSON PHASE II LANDFILL CLOSURE COST ESTIMATE**	**PLANT NAME:** DB WILSON	**CLOSURE TYPE:** CAP IN PLACE	**SHEET:** 1	**REV. NO.:** 1
	SUBJECT: Preliminary Project Costs Sheets	**UNIT NAME:** PHASE II	**CLOSURE METHOD:** CAP IN PLACE	**CLOSURE YEAR:** 2021	**AECOM JOB NO.:** 60631499
	ACTIVITY: **Close-in-Place Costs**	**CLOSURE OPTION:** CAP IN PLACE	**LAST UPDATED BY:** AGH	**DATE LAST MODIFIED:** 08/26/21	**REVIEWED BY:** TAK

KEY ASSUMPTIONS

The following key assumptions and limitations are associated with the project design, implementation and performance:

1	The cost estimates were prepared using 2020 dollars and do not include any escalation.
2	No costs to improve the existing sediment basins or to regrade the perimeter ditch have been included.
3	The unit rate costs are based on AECOM experience, RS Means, and recent quotes from Watershed Geo on a hypothetical project of this size.
4	No costs to convey seepage to existing treatment system have been included.
5	It is assumed that the existing perimeter ditch profile provides adequate drainage, and no significant improvements are required.
6	Abandonment of existing structures/piping includes the demolition of existing pipes and inlets/outlet structures, and converting the resulting trench into a rip rap flume. There may be some grouting of outlet pipes that extend beyond the limits of waste.
7	Cap cross section for the CCR landfill will consist of (from bottom to top): cover soil / geomembrane / closure turf / sand infill.
8	Statements of Probable Construction Cost prepared by AECOM represent AECOM's judgment as a design professional familiar with the construction industry. It is recognized, however, that neither AECOM nor the Owner has control over the cost of labor, materials or equipment nor over the contractor's methods of determining the bid price or other competitive bidding, market, or negotiating conditions. Accordingly, AECOM cannot and does not warrant or represent that proposals, bids or actual construction costs will not vary from any statement of Probable Construction Cost or other estimates or evaluations prepared by AECOM.

Rev. 8-26-2021

DB WILSON SITEWIDE LANDFILL CAP

POST CLOSURE CARE COST ESTIMATE - ENTIRE FOOTPRINT - TOTAL PC PERIOD

Consideration	Phase I Post Closure Care Cost 2020 Dollars	Phase II Post Closure Care Cost 2020 Dollars
Ground Water Monitoring	$ 8,000	$ 24,000
Leachate Treatment	$ 93,000	$ 80,000
Operation and Maintenance (Sand Maintenance, Inspections, etc.)	$ 18,000	$ 18,000
Engineering Design / Utilities (5%)	$ 5,950	$ 6,100
Subtotal	$ 124,950	$ 128,100
Contingency (10%)	$ 13,000	$ 13,000
ANNUAL POST CLOSURE CARE TOTAL =	**$ 137,950**	**$ 141,100**
Number of years	**$ 5**	**$ 30**
PER ACRE ANNUAL COST =	**$ 1,339.32**	**$ 1,397.03**
TOTAL POST CLOSURE COST =	**$ 689,750.00**	**$ 4,233,000.00**
